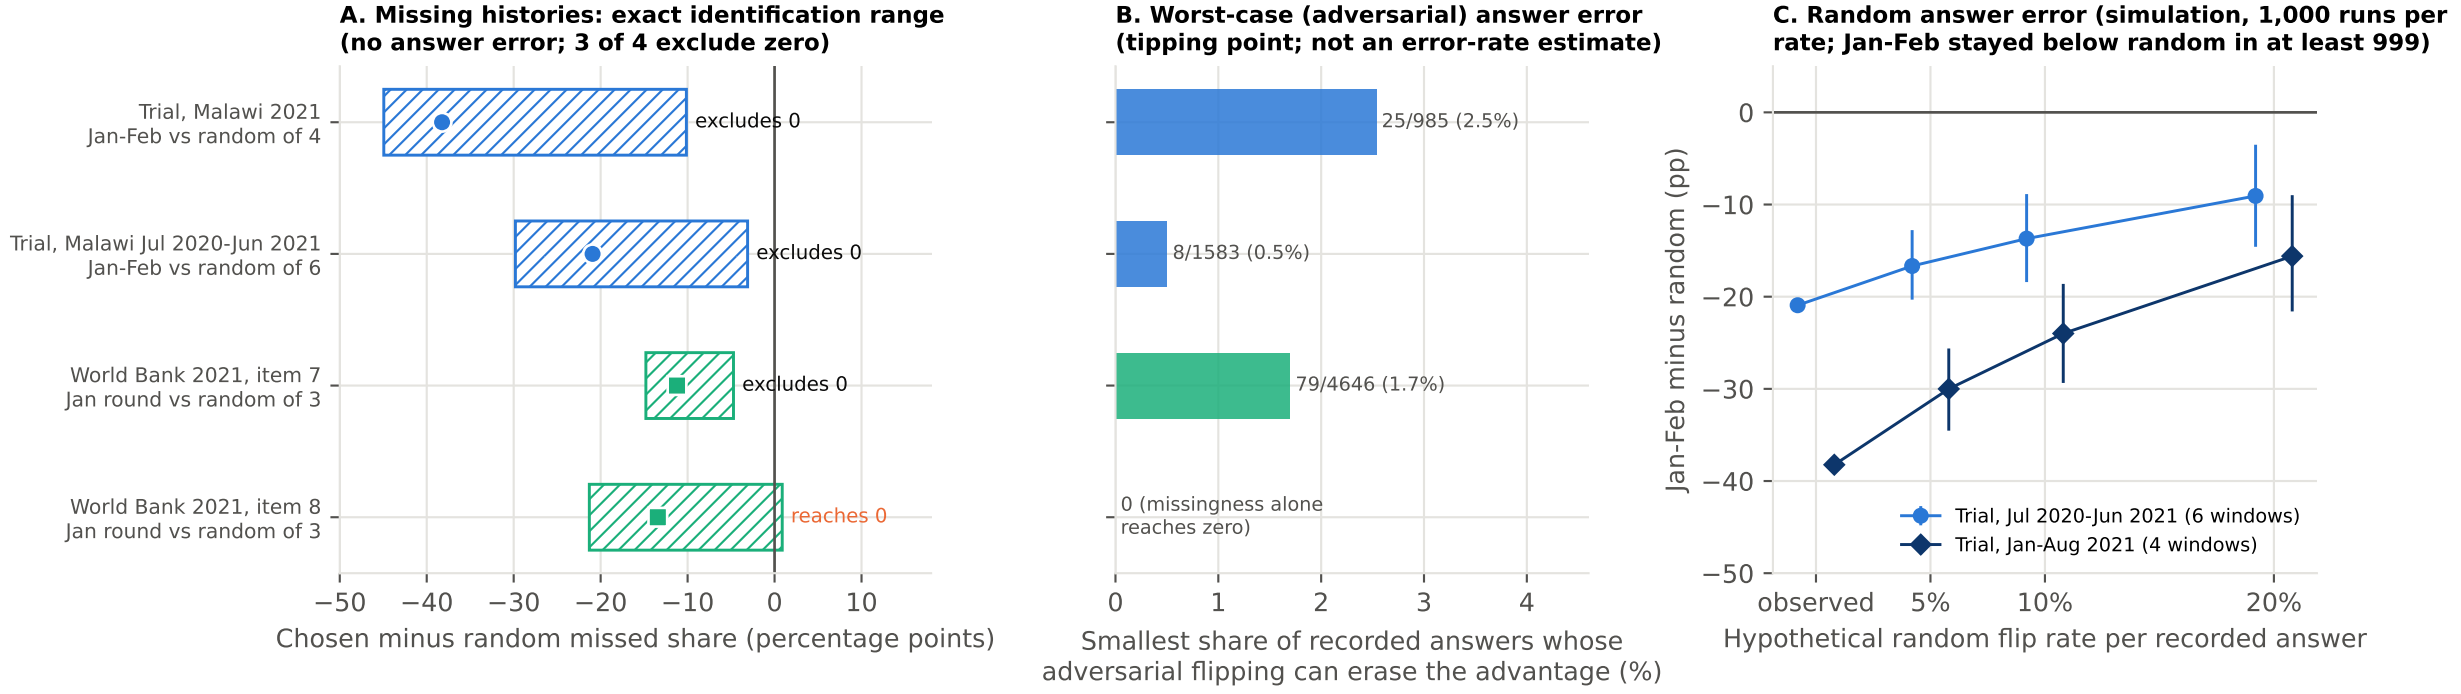
Robustness of screening-timing comparisons to missing histories and hypothetical answer error



A: hatched bars are exact identification ranges over all completions of missing screens (not confidence intervals); dot = complete-case value. The World Bank item 8 comparison reaches zero. B: answers flipped in the most damaging possible way; a tipping point is not an estimate of real error. C: answers flipped at random at hypothetical rates; dots = mean, whiskers = 2.5th to 97.5th percentiles of the simulated difference; trial (HHS) analyses only. No claim is made about which error mechanism operates.
